Introduction

Pantherella's production was featured by BBC Inside the Factory, revealing how the organisation produces socks in a factory in the heart of Leicester (BBC, 2021).

Established in 1937, the organisation possesses a USP based around authentic premium British-made socks, prioritising craftsmanship and high-quality materials

(Pantherella, 2025). This report provides an operational, analytical toolkit, where

section one provides a detailed overview of the company's current production

processes, evaluating its current setup and advocating for potential improvements.

Furthermore, it highlights control variabilities affecting the quality of the final product.

Section two provides calculations based on forecasting, forecasting error and decision-

making, exploring the best suitable options while considering Pantherella's values and

current process capabilities.

The Process

1.1 Process Map

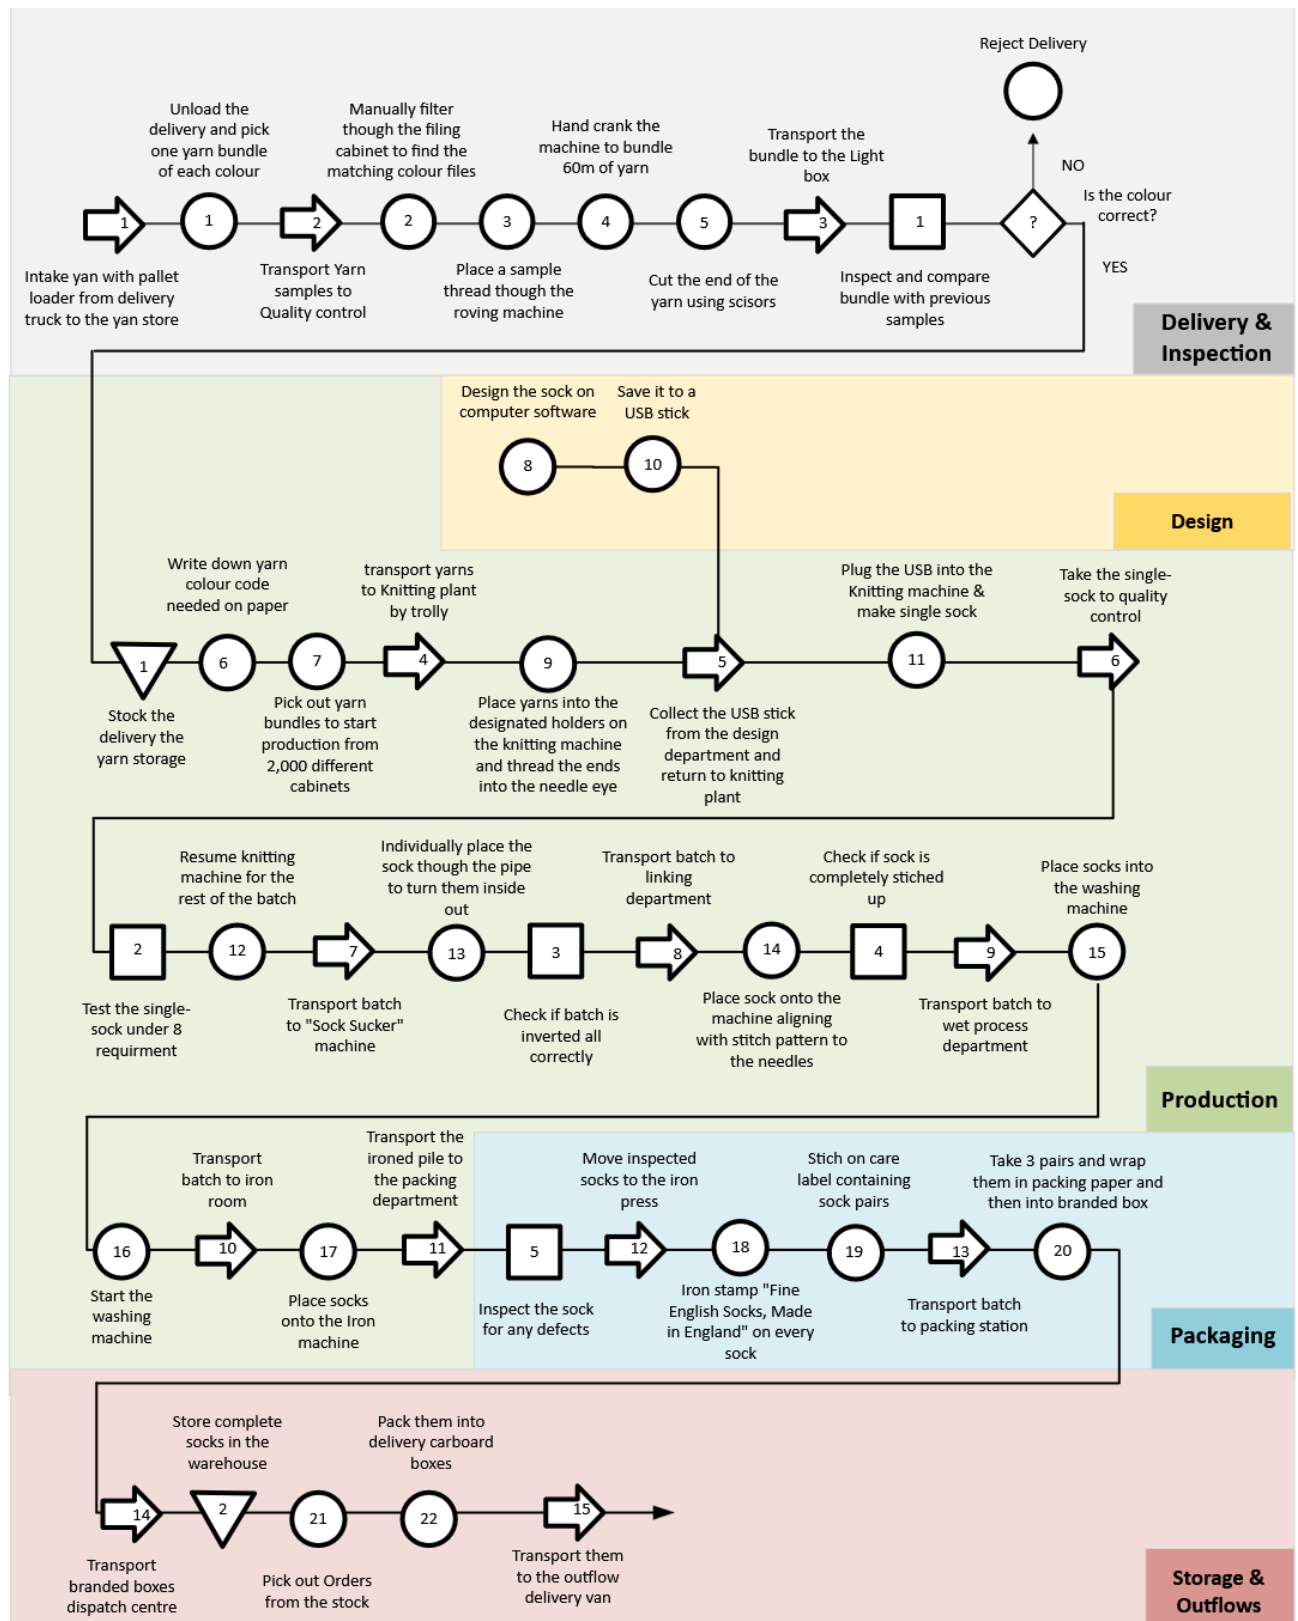

Figure 1: Initial Sock Process Map (Created using Visio)

1.2 Evaluating the Process

| <u>Changes</u> | <u>Processes Effectuated</u> | <u>Reason</u> | <u>Next Actions</u> |
|---|---|---|--|
| Roving Process <u>Eliminate</u> |  | Set up for raw material verification is highly time-consuming, requiring individuals to set up and hand crank a roving machine for a yarn bundle sample for every colour delivered. | Agreement with the supplier to supply yarn sample bundles within deliveries. |
| Stocking and Picking <u>Reduce</u> |  | Around 2,000 different cabinets and 1km of coded shelves can be time-consuming to pick. Additionally, it reduces raw material handling variability where bundles are stored in incorrect locations. | Investment In RFID hand-held devices and tags Passive RFID tags = (\$0.5 x 2000) = \$1,000 Handheld reader = \$250 Investment = \$1,250 |
| Unecessary Machine Processing <u>Eliminate</u> |  | Increase investment and reliance on all-in-one machines. Eliminating the subsequent steps where skill variability plays a critical role would be beneficial. | All-in-one machinery 64 machines x \$33,000 = \$2,112,000 Long-term investment |
| Overproduction <u>Reduce</u> |  | Three million worth of stock can satisfy 4 months' worth of demand. Overproduction and overstocking lead to expensive holding costs. | Shifting to a Make-to-Order framework for big bulk orders with high variety |

Figure 2: Process improvement summary table

A critical process in sock production is inspecting the raw material delivered by the supplier. This is done by collecting a sample of different-coloured yarns, transporting them to the quality control room, and manually preparing a 60-meter bundle of thread to compare under a light box against the colour-specific file that contains a historical record of previous deliveries (BBC, 2021). Verification of colour variability is critical as Pantherella charges a premium price (£15-£75) for a single pair of socks, and consumers expect the highest quality standards (Pantherella's, 2025). Retailers may use different lighting within stores that can give an altered appearance, not as intended, leading consumers to purchase them assuming they look a certain way, to be then disappointed when the socks are taken under different lighting, mismatching their visual expectations (Summers, 2021; Slack, 2018).

The paper-based historical record-keeping allows the possession of a valuable physical archive. However, the current process is highly time-consuming, requiring the manager to repeat the entire process for every colour ordered. This can be refined by eliminating the roving and hand-cranking of the bundles' steps, which are necessary non-value-adding processes not directly contributing to the value of the sock but are needed for the inspection (Hillier, 2021), by outsourcing the sample requirement externally to the supplier. The existing contract can be altered to provide samples within deliveries, streamlining and reducing the time needed to prepare the inspection while allowing independent colour verification.

Another refinable process is storing and selecting raw materials in the yarn storage, which holds around 30 tonnes in approximately 2,000 different cabinets stored on a kilometre of coded racking (BBC, 2021). A recommendation is to invest in handheld RFID readers that can accurately detect the correct location of the cabinet, providing the user with an optimised route (Hassan, 2012). The readers work by detecting a radio wave of corresponding RFID tags that should be located next to the cabinets, replacing the inefficient task of aimlessly walking, trying to find the correct number and providing a navigational tool that can also replace the paper process (Hassan, 2012), where the items can be ticked off on the device once the task is completed (Chatzistefanou, 2023). This is essential as it reduces the chances of errors and process variabilities within raw material handling, eliminating the possibility of accidentally writing the wrong four-digit code down or placing similarly coloured yarns in the wrong cabinets.

Such errors can affect quality as misidentified yarns may proceed to production, creating inconsistencies and defects within the final product (Slack, 2018).

Pantherella adopts a worker-paced line firstly using 64 knitting machines to create the sock base, which is later vacuumed inside out and finally to the shaping area to needle and close the toe section (BBC; 2021; Nichol, 2023; Shapiro, 2013). The initial process is conducted by machine, but subsequent stages rely heavily on skilled labour, increasing the chances of skilled variability but also enabling exceptional craftsmanship, a core value deeply rooted in Pantherella (Pantherella, 2025). Variations within quality can occur during this process as skill discrepancies and fatigue are likely to reduce the accuracy of placing the needles precisely in-between the correct thread, leading to deviations of missed threads that are difficult to identify and may lead to holes affecting the quality of the product (Slack, 2018).

In a recent blog involving the production manager Simon, the organisation announced a shift towards modern machinery designed to streamline the production stages, consolidating multiple tasks into a single effective process (Nichol, 2023). Shifting production reliance to an all-in-one machine eliminates the consequential transporting, operating, and inspection processes, reducing the sock's lead time (Hillier, 2021). Although the machines are extremely costly, around £30,000 per, they reduce the potential for human errors, providing a more consistent quality (Evans, 2014). Process variability shifts from human skill towards machine setup, and adequate training is needed for operators.

Although the packing stages are extensive, Pantherella should maintain and convey a heightened-quality appearance. A recent survey indicated that “72% of consumers consider packaging as one of the biggest influences when purchasing premium or giftable items” (Punchard, 2024). The packing processes provide direct consumer value to the final product and, therefore, will not be changed.

Pantherella holds £3 million in completed sock stock inventory, enough to meet four months of demand (BBC, 2021). Holding large inventory volumes can support the business during periods of unexpected demand. However, the current city factory location emphasises that holding costs is expensive. Stock is difficult to liquidate quickly, and enormous capital is locked up that can be used to increase investments in modern machinery (Silver, 2016). Considering the over 1,300 different seasonal options available and the relatively short 17-hour production time, it is sensible to push the decoupling point back to the beginning of the process, making large batch orders once they are confirmed, reducing the complexity of forecasting for a wide range of variations and the chances of overproduction (Bowersox, 2020; Olhager, 2003). Pantherella can maintain the production of popular sellers in a low-capacity steady-state production (Slack, 2021). However, larger orders with wide varieties should be produced once placed, minimising unnecessary storage.

1.3 Evaluations in Practice

| Process | Operations | Inspection | Transport | Storage | Delays |
|--------------------------|------------|------------|-----------|----------|----------|
| Initial Process | 22 | 5 | 15 | 2 | 0 |
| Improved process | 16 | 3 | 13 | 2 | 0 |
| Processes Removed | 6 | 2 | 2 | 0 | 0 |

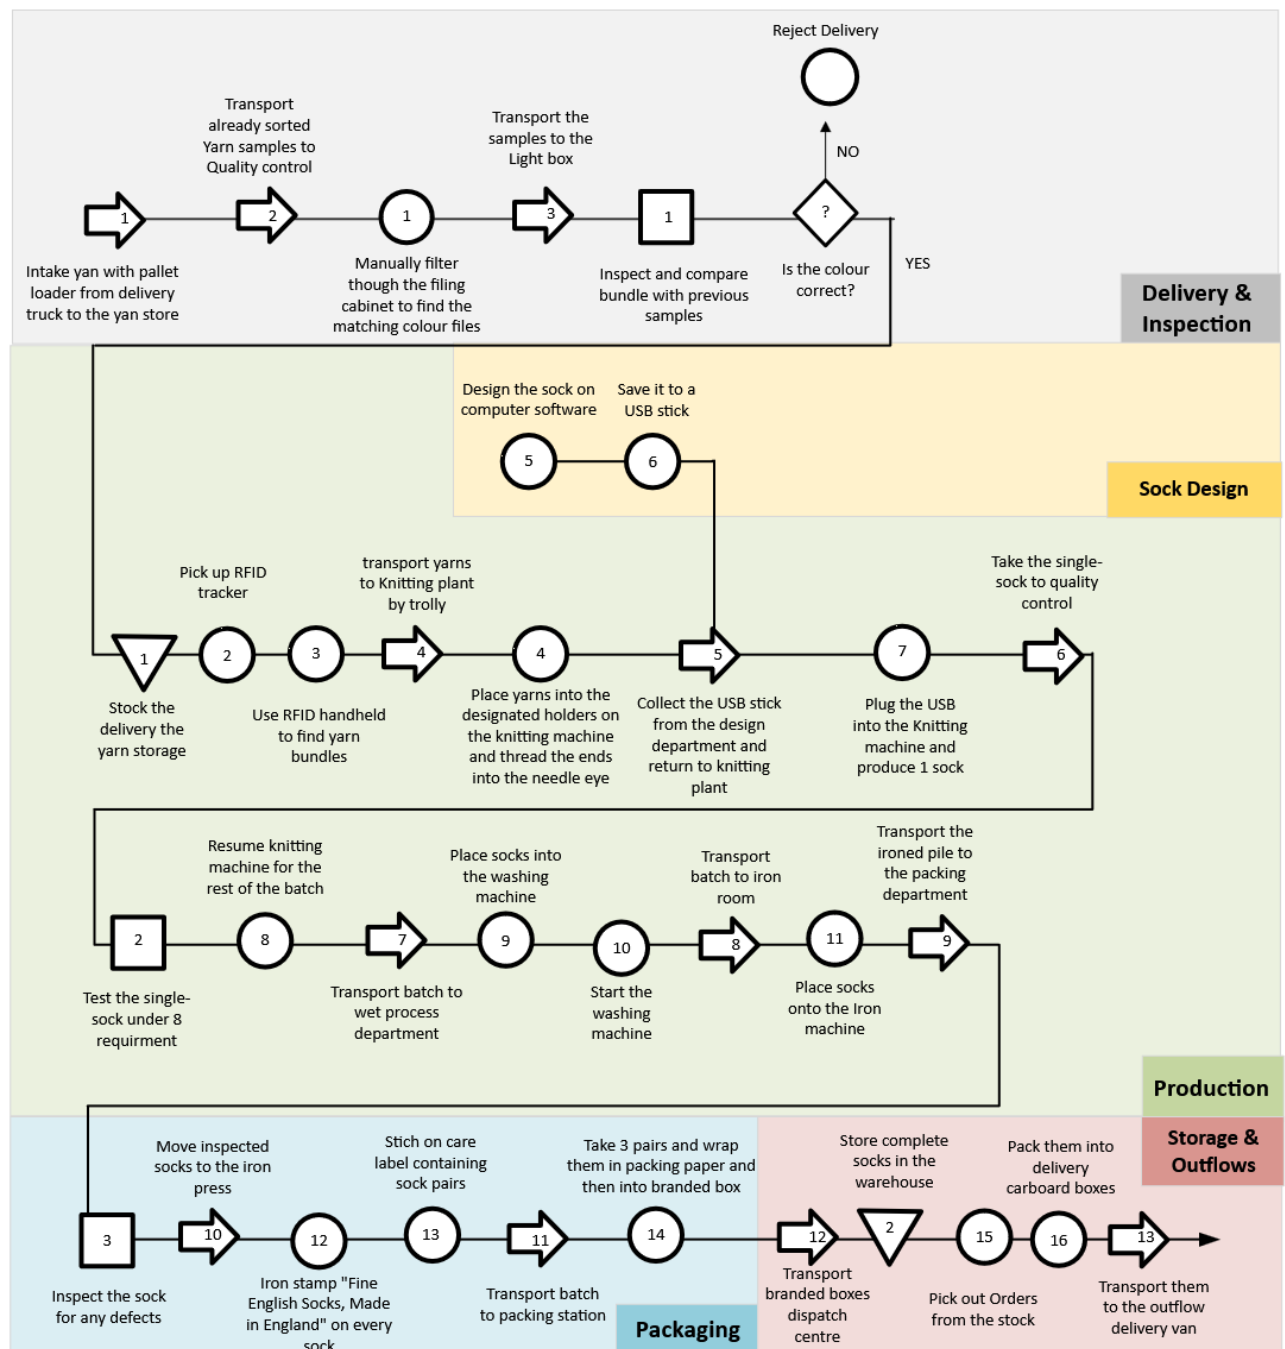

Figure 3: Improved Process Map (Created by C21084397, using Visio)

Forecasting and Decision-Making

2.1 Forecasting

| Period | Number of Faulty products |
|--------|---------------------------|
| Jan | 30 |
| Feb | 35 |
| March | 55 |
| April | 68 |
| May | 64 |

Forecasting for June

| Period | Naïve | Three Moving Average | SES |
|--------|-------|----------------------|-------|
| June | 64 | 62.33 | 56.77 |

a. Naïve method

$$F_t = A_t - 1$$

$$F_t = 64$$

b. 3-period moving average

$$F_t = \frac{A_{t-1} + A_{t-2} + A_{t-3}}{3}$$

$$F_t = \frac{64 + 68 + 55}{3}$$

$$F_t = 62.33$$

c. Exponential Smoothing with Constant of 0.4

| Period | Number of Faulty products | SES |
|--------|---------------------------|-------|
| Jan | 30 | 30 |
| Feb | 35 | 30 |
| March | 55 | 32 |
| April | 68 | 41.8 |
| May | 64 | 51.28 |
| June | 64 | 56.77 |

SES formula:

$$F_t = \alpha A_{t-1} + (1 - \alpha)F_{t-1}$$

1) Jan:

$$F_1 = 30$$

2) Feb:

$$F_2 = 0.4 \times 30 + 0.6 \times 30 = 30$$

3) March:

$$F_3 = 0.4 \times 35 + 0.6 \times 30 = 32$$

4) April:

$$F_4 = 0.4 \times 55 + 0.6 \times 32 = 41.8$$

5) May:

$$F_5 = 0.4 \times 68 + 0.6 \times 41.8 = 51.28$$

6) June:

$$F_6 = 0.4 \times 64 + 0.6 \times 51.28 = 56.77$$

The most suitable method for forecasting faulty products would be the Naïve method as it places greater significance on the last periods of recorded data (Armstrong, 2001).

With a gradual increase but no clear trend or seasonality traits within the data, the simple yet effective method can respond faster to erratic fluctuations caused by various factors affecting quality inconsistencies, such as their skilled workforce, quality of raw material or machine variabilities (Hyndman, 2018). By identifying the issue sooner, Pantherella can solve the problem promptly, preventing more unnecessary waste of premium sock raw materials such as cashmere and silks that can lead to significant financial losses for the company (Carvalho, 2023; Slack, 2022). If faulty products slip

through the quality inspections, it could jeopardise their well-established 88-year reputation for quality socks (Pantherella, 2025).

The three-moving average and Simple exponential smoothing, which place a 60% weight on the previous month's forecast, significantly dampen the overall results (Ostertagová, 2011). Hindering the quality control teams' visibility in identifying causation factors swiftly, resulting in a delayed response.

2.2 Forecasting Accuracy

a. Old Machine

Old Machine

| Month | Demand | Old Machine | Absolute Error | Squared Error | Absolute percentage error |
|-------|--------|-------------|------------------|---------------|----------------------------|
| 1 | 592 | 590 | $ 592-590 = 2$ | $2^2 = 4$ | $ 592-590 / 592 = 0.34\%$ |
| 2 | 550 | 562 | $ 550-562 = 12$ | $12^2 = 144$ | $ 550-562 / 550 = 2.18\%$ |
| 3 | 565 | 572 | $ 565-572 = 7$ | $7^2 = 49$ | $ 565-572 / 565 = 1.24\%$ |
| 4 | 573 | 570 | $ 573-570 = 3$ | $3^2 = 9$ | $ 573-570 / 573 = 0.52\%$ |
| 5 | 590 | 597 | $ 590-597 = 7$ | $7^2 = 49$ | $ 590-597 / 590 = 1.19\%$ |
| 6 | 592 | 593 | $ 592-593 = 1$ | $1^2 = 1$ | $ 592-593 / 592 = 0.17\%$ |
| Mean | | | 5.33 | 42.67 | 0.94% |

b. New Machine

New machine

| Month | Demand | New Machine | Absolute Error | Squared Error | Absolute percentage error |
|-------|--------|-------------|------------------|---------------|----------------------------|
| 1 | 592 | 595 | $ 592-595 = 3$ | $3^2 = 9$ | $ 592-595 / 592 = 0.51\%$ |
| 2 | 550 | 565 | $ 550-565 = 15$ | $15^2 = 225$ | $ 550-565 / 550 = 2.73\%$ |
| 3 | 565 | 576 | $ 565-576 = 11$ | $11^2 = 121$ | $ 565-576 / 565 = 1.95\%$ |
| 4 | 573 | 575 | $ 573-575 = 2$ | $2^2 = 4$ | $ 573-575 / 573 = 0.35\%$ |
| 5 | 590 | 594 | $ 590-594 = 4$ | $4^2 = 16$ | $ 590-594 / 590 = 0.68\%$ |
| 6 | 592 | 593 | $ 592-593 = 1$ | $1^2 = 1$ | $ 592-593 / 592 = 0.17\%$ |
| Mean | | | 6 | 62.67 | 1.07% |

c. Summary Table

Error Summary Table

| Machine | MAE | MSE | MAPE |
|---------|------|-------|-------|
| Old | 5.33 | 42.67 | 0.94% |
| New | 6 | 62.67 | 1.07% |

Based on the calculations, the old machine should be chosen as it exhibits smaller forecasting errors (Hillier, 2021). A smaller forecasting error in this situation suggests that the old machine is better at aligning performance to Pantherella's current demand, which is critical to minimise the chances of overproducing or underproducing. Producing excess inventory would elevate their already £3 million worth of stock and lead to unnecessary holding costs. Additionally, their more than 1,300 designs risk unsold variations, which may be difficult to liquidate. On the other hand, underproducing fails to meet demand, leading to stockouts that would consequentially impact customer service levels and undermine Pantherella's brand reputation for customer satisfaction (Pantherella, 2023).

While the new machine may perform at a better standard and offer additional modern features, its current performance is less in line with Pantherella's current needs. If demand exceeds the old machine's output capabilities, a re-evaluation is needed to justify the additional £30,000 purchasing cost for the new machine.

2.3 Decision-Making

Payoff Table

| | Good | Medium | Poor |
|----------|------|--------|------|
| Design A | 100 | 20 | 20 |
| Design B | 70 | 50 | -40 |
| Design C | 90 | 40 | -20 |

Regret Matrix

| - | Good | Medium | Poor |
|----------|-------------------|------------------|-------------------|
| Design A | $100 - (100) = 0$ | $50 - (20) = 30$ | $20 - (20) = 0$ |
| Design B | $100 - (70) = 30$ | $50 - (50) = 0$ | $20 - (-40) = 60$ |
| Design C | $100 - (90) = 10$ | $50 - (40) = 10$ | $20 - (-20) = 40$ |

| | | |
|----------|---------------------------------|---------------------------------|
| Design A | $\text{Max } (0, 30, 0) = 30$ | $\text{Min } (30, 60, 40) = 30$ |
| Design B | $\text{Max } (30, 0, 60) = 60$ | |
| Design C | $\text{Max } (10, 10, 40) = 40$ | |

Based on the calculations, design A (30) should be selected, as it possesses the smallest possible regret in the worst-case scenario. Minimax is appropriate for Pantherella as changing the process requires substantial capital and resource investments. It ensures that even in the worst-case scenario, the company will face the smallest possible loss relative to the best outcome possible (Anderson, 2023).

A risk-averse mindset minimises the chances of potential consequences if Pantherella faces undesirable outcomes (Hillier, 2021). This is particularly important as Pantherella relies on skilled employees, and the factory city location indicates high operational costs. Minimax reduces the chances of facing higher-than-intended risk levels that could lead to financial difficulties and potential employee layoffs, an extremely difficult

decision due to employees possessing specific skills while having a deep-rooted generational heritage (Pantherella, 2025). Additionally, process redesign for socks may require investing in specialised customised machinery that is extremely expensive, which, in undesirable outcomes, will be challenging to resell onto second-hand markets or forced to sell for scrap value, regretting and losing significant capital (Vranakis, 2012).

Conclusion

To conclude, this report provides an in-depth look into the production processes of Pantherella's socks alongside interpreted forecasting and decision-making calculations. By analysing their current operational processes, it was evident that the organisation possesses inefficiencies, notably the initial inspection process, inventory control management, reliance on skilled labour, and outdated machinery.

Recommendations include outsourcing the raw material samples, implementing an RFID handheld device, increasing investments into all-in-one machinery and rethinking how the organisation could reduce the quantity of stocked finished goods. Within section two, the Naïve method is best for forecasting faulty products, as it places a greater significance on the last actual demand period. The old machine should also be chosen due to it being better in line with current demand patterns, and lastly, design A as it minimises potential regret.
